Report Documentation Page				Form Approved OMB No. 0704-0188	
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

Cooperativity at the monomolecular level binding of B or C to the common partner A affects binding of the other

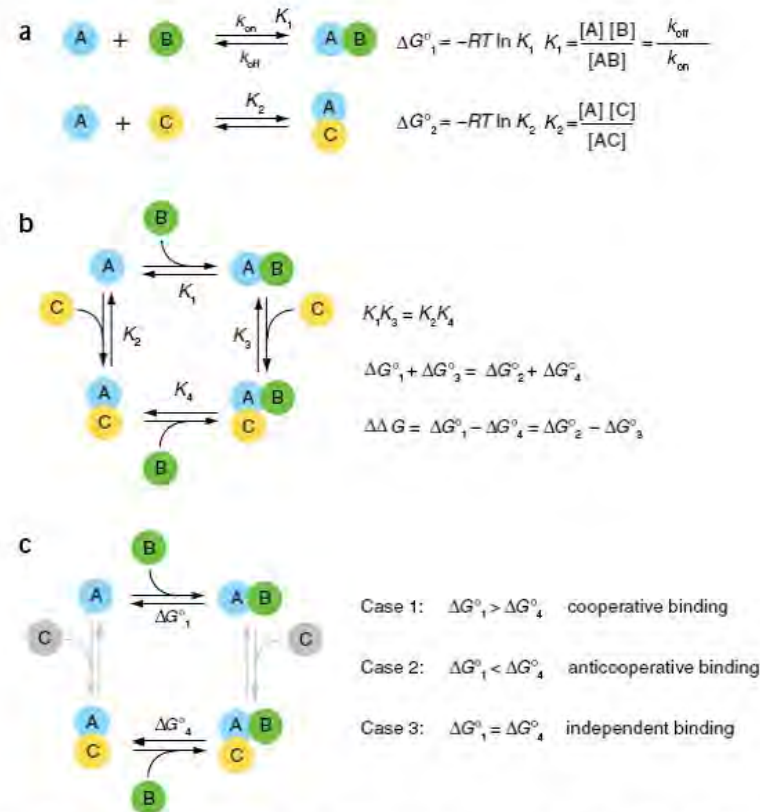

Figure 1 Thermodynamic cycles and cooperativity. (a) Hypothetical set of bimolecular complexes between component A and two other components (B and C), with the rate constants, equilibrium constants and free energies for complex formation. (b) A thermodynamic cycle for formation of the ternary complex ABC by two different possible routes: either B binds first, or C binds first. There are four equilibrium constants that describe the formation of the various complexes. Because they converge on the common product ABC, the thermodynamics must be independent of the pathway chosen around the cycle, and constraints are placed on the relative values of the equilibrium constants and hence the free energies. The thermodynamic coupling free energy ($\Delta \Delta G$) gives the difference between binding of one component in the presence of the other. (c) Definition of cooperativity in terms of binding of B in the presence or absence of C. The two vertical binding reactions are gray to emphasize the comparison of ΔG°_1 and ΔG°_4 . If B binds better in the presence of C, the binding is cooperative. If B binds worse in the presence of C, the binding is anticooperative. In the third case, binding of B is independent of C, and there is no cooperativity.

Cooperativity/heterogeneity

1. complex interactions among identical ligands binding to multiple sites on an oligomeric protein--oxygen binding to hemoglobin.

Homotropic *allosteric* regulators—e.g. O₂

Heterotropic *allosteric* regulators—e.g. 2,3 BPG

2. the thermodynamics of macromolecular conformational transitions--protein folding or nucleic acid helix-coil transitions.

3. the thermodynamics of forming multicomponent complexes—multimeric complexes, surface interactions, cellular communication, organism organization, multicellular dynamics, social structures

Interaction of Hemoglobin with Three Ligands: Organic Phosphates and the Bohr Effect

(Haldane coefficient/2,3-diphosphoglycerate/linkage equations/allosteric effect/oxygen binding)

RUTH E. BENESCH AND HARVEY RUBIN

Department of Biochemistry, Columbia University, College of Physicians & Surgeons, New York, N.Y.

Communicated by Harden M. McConnell, April 16, 1975

ABSTRACT The assumption that the Bohr coefficient ($\Delta \log p_{50}/\Delta \text{pH}$) is equal to the Haldane coefficient (ΔH^+) of hemoglobin is shown to be incorrect in the presence of allosteric effectors such as 2,3-diphosphoglycerate. The theoretical relation between the two coefficients in the presence of 2,3-diphosphoglycerate is derived. Experimental data on the variation of both coefficients with diphosphoglycerate concentration are presented and shown to be in agreement with prediction.

Therefore, the liberation of diphosphoglycerate on oxygenation must lead to an increase in its activity with increasing oxygenation, and Eqs. 1 and 2 can no longer apply.

It is the purpose of this paper to examine the relation between the Bohr and Haldane effects in the presence of 2,3-diphosphoglycerate.

RESULTS AND DISCUSSION

Box 1 A timeline showing evolution of allostery as a concept

The timeline (Fig. 1) includes some of the key experiments and realizations of the field and some insight into how the mentality of the field has shifted.

1903—The Bohr effect (sigmoidal binding curve of hemoglobin to O_2 was observed).

1910—A. Hill formulates the Hill equation to describe the sigmoidal binding of O_2 to hemoglobin.

1958—First X-ray structure (sperm whale myoglobin) solved by M. Perutz and Sir J. Cowdery Kendrew⁷⁸.

1950s—Repression of gene expression, covalent modification of enzyme activity, and feedback inhibition of enzymes are discovered⁷⁹.

1963—J. Monod renames regulatory sites 'allosteric sites.'

1965—J. Monod, J. Wyman and J.-P. Changeux propose a theoretical model of concerted allosteric transitions (MWC model)¹.

1966—D. Koshland, G. Nemethy and R. Filmer propose the sequential model for allosteric transitions (KNF model)⁸⁰.

1984—Allosteric regulation in the absence of conformational change is proposed¹².

1980s—Protein folding studies lead to the concept that proteins exist in different conformations in an "energy landscape"⁸¹.

1990s—Mutations, covalent modifications and changes in conditions such as pH are included as allosteric effectors.

1999—Allosteric networks in the PDZ domain proposed by R. Ranganathan⁵⁰.

2006—Negative allostericity reported in the absence of conformational changes⁶⁴.

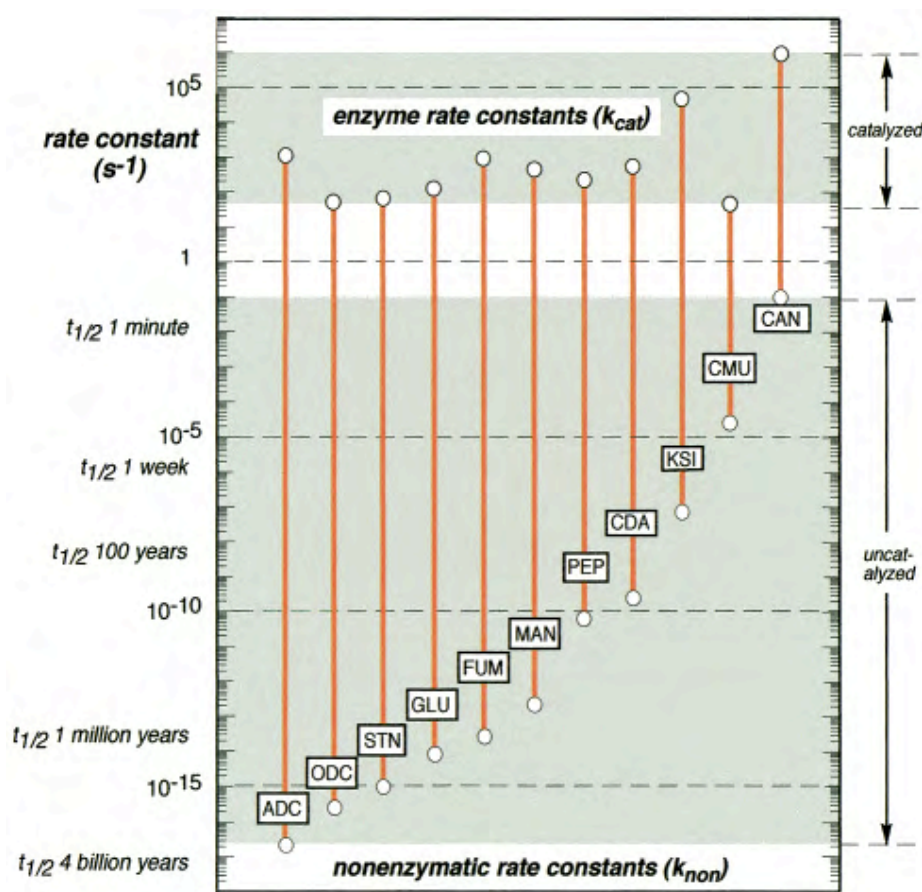

Figure 1 Timeline showing the discovery and progression of the concept of allosteric regulation in proteins.

Logarithmic scale of k_{cat} and k_{non} values for representative reactions at 25 °C. The length of each vertical bar represents the rate enhancement by each enzyme

ADC) arginine decarboxylase;
 ODC) orotidine 5'-phosphate
 decarboxylase;
 STN) staphylococcal nuclease;
 GLU) sweet potato α -amylase; FUM)
 fumarase;

The Stringent Response is mediated by two opposing Rel_{Mtb} activities which must be tightly regulated

1) pppGpp synthesis:

2) pppGpp hydrolysis:

pppGpp alters RNAP kinetics and mediates the transcriptional response to environmental conditions to which Mtb is exposed

The RAC Allosterically Activates Transferase Activity

	K_{ATP} (mM)	K_{GTP} (mM)	k_{cat} (s ⁻¹)	k_{cat}/K_{ATP} (mM ⁻¹ s ⁻¹)	k_{cat}/K_{GTP} (mM ⁻¹ s ⁻¹)
Rel_{Mtb} (Basal Level)	2.0	1.4	1.2	0.6	0.9
Rel_{Mtb} + Ribosome•UtRNA•mRNA	0.5	0.3	24.7	54.8	79.6

**RAC = Rel_{Mtb} Activating Complex
Ribosome•Uncharged tRNA•mRNA**

Heterogeneity even within a single molecule

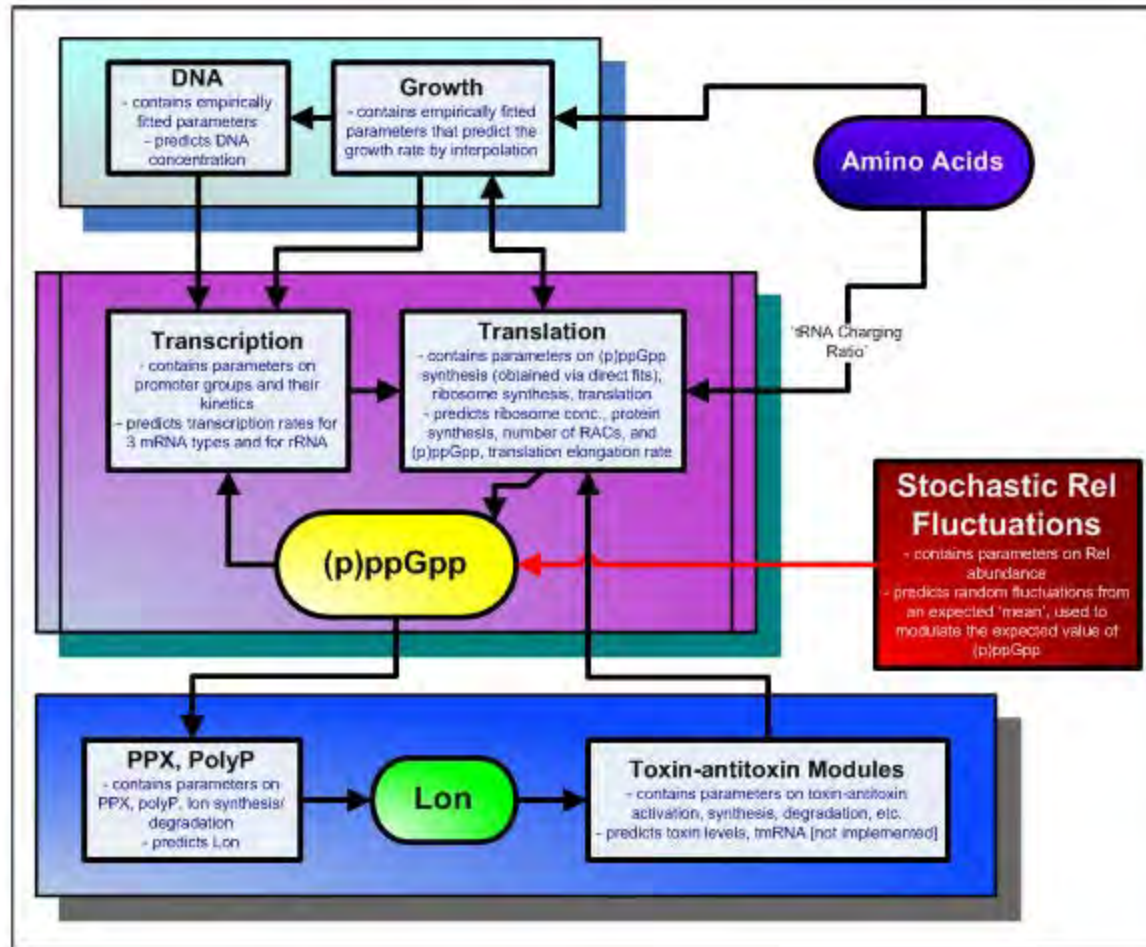

Figure 1: Summary of Rel_{Mtb} truncated. Full-length Rel_{Mtb} protein is at the top followed by the different truncated proteins. Amino acid numbers are at the beginning and end of each fragment and corresponding activity is listed below. 87-187 overlapping site is noted in the full-length Rel_{Mtb} .

Cooperativity, heterogeneity, stochasticity

$$\frac{1 \ \text{---}}{\frac{1 \ A \ 0 \ \text{---} \ C' A' B'}{\langle \text{---} 0 \rangle}} \Rightarrow \frac{1 \ A \ 0}{\langle \text{---} 0 \rangle}$$

Figure 2

Why reversible?

Minimal energy expense

Detection and correction of intrusion

Error checking by reversing computation
to recreate inputs

Bidirectional debugging

In principle it can take minimal energy to go through a biochemical gate

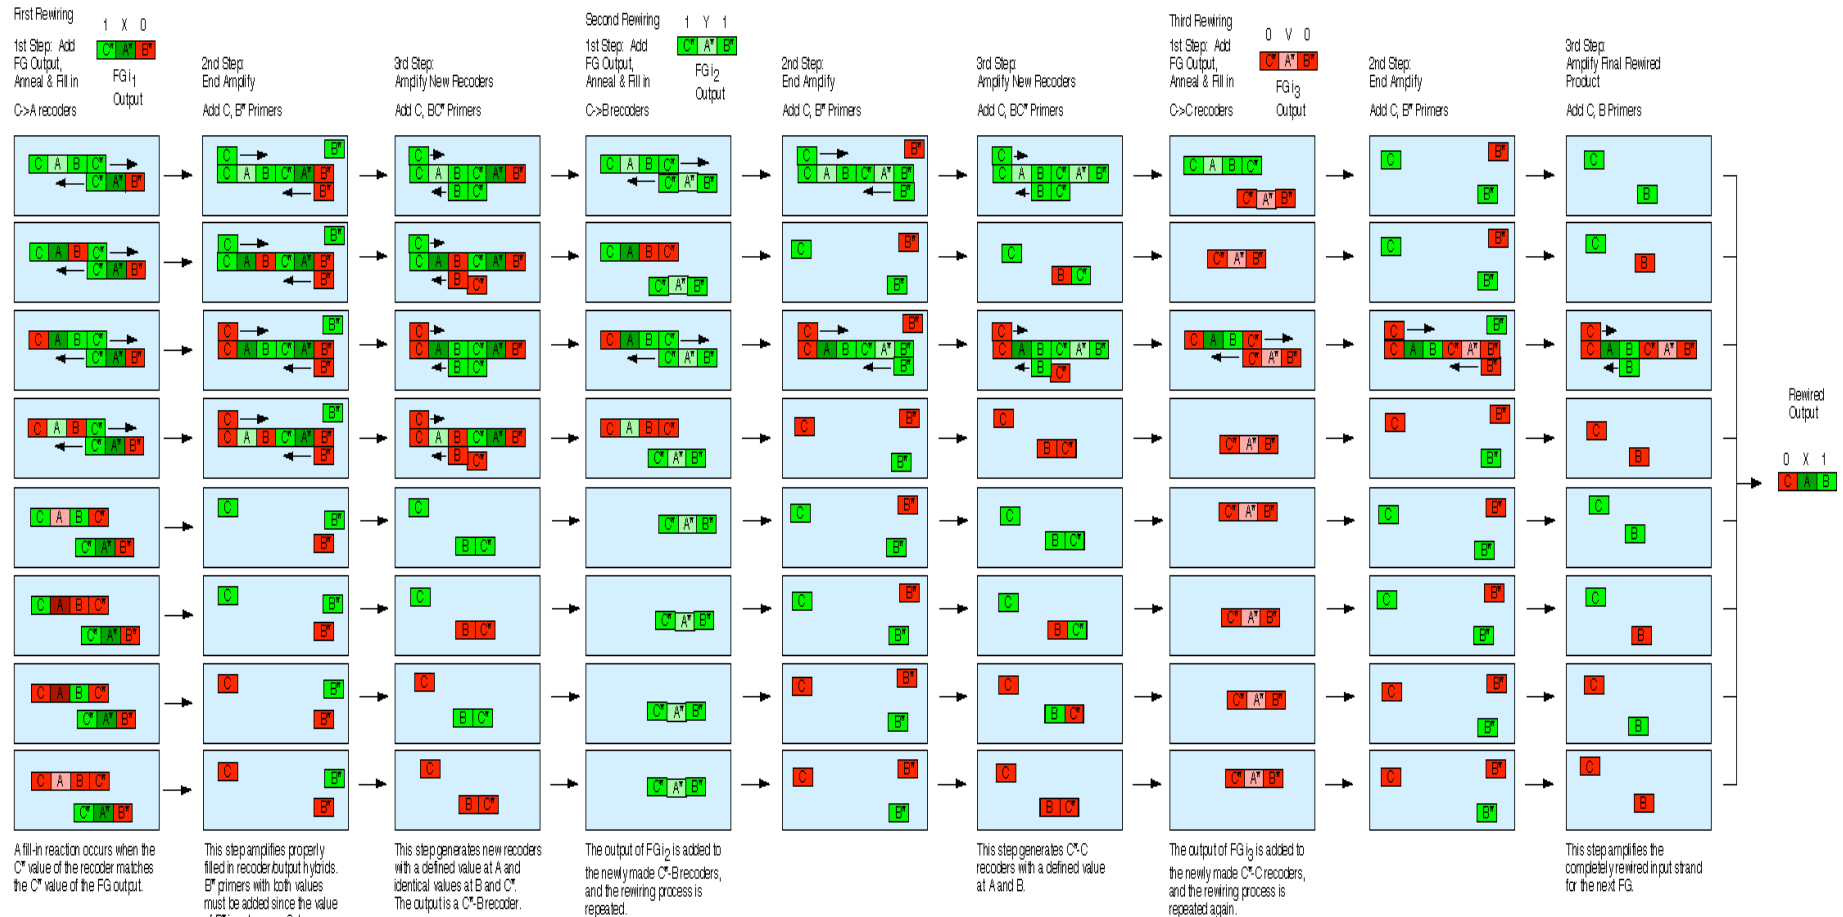

$$\Delta G = kt \ln[\text{dNTP}/\text{PPi}]$$

If dNTPs are just 1% over the equilibrium value:

$$\Delta G = kt \ln[10.1/10] \quad \text{or about } 0.01kT$$

a modification of an idea in Bennett and Landaur's Sci. Am paper—suggested using RNA

We synthesized the oligonucleotides and ran the reactions
